In [1]:
```
# import the liberies
import numpy as np
import pandas as pd
%matplotlib inline
import matplotlib.pyplot as plt
```

Creating DataFrames

From a list of dictionaries (constructed row by row)

In [2]:
```
list_of_dicts = [
     {"name": "Ginger", "breed": "Dachshund", "height_cm": 22,"weight_kg": 10, "dat
    {"name": "Scout", "breed": "Dalmatian", "height_cm": 59,"weight_kg": 25, "date_
]
new_dogs = pd.DataFrame(list_of_dicts)
new_dogs
```

Out[2]:

	name	breed	height_cm	weight_kg	date_of_birth
0	Ginger	Dachshund	22	10	2019-03-14
1	Scout	Dalmatian	59	25	2019-05-09

From a dictionary of lists (constructed column by column)

In [3]:
```
dict_of_lists = {
     "name": ["Ginger", "Scout"],
     "breed": ["Dachshund", "Dalmatian"],
     "height_cm": [22, 59],
     "weight_kg": [10, 25],
     "date_of_birth": ["2019-03-14","2019-05-09"]  }
new_dogs = pd.DataFrame(dict_of_lists)
new_dogs
```

Out[3]:

	name	breed	height_cm	weight_kg	date_of_birth
0	Ginger	Dachshund	22	10	2019-03-14
1	Scout	Dalmatian	59	25	2019-05-09

Reading and writing CSVs

CSV = comma-separated values.

Designed for DataFrame-like data.

Most database and spreadsheet programs can use them or create them.

In [4]:
```
avocado = pd.read_csv(r'D:\14th nov  avocado resume project\14th\RESUME PROJECT --
```

In [5]:
```
avocado.head()
```

Out[5]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	Large Bags
0	0	2015-12-27	1.33	64236.62	1036.74	54454.85	48.16	8696.87	8603.62	93.25
1	1	2015-12-20	1.35	54876.98	674.28	44638.81	58.33	9505.56	9408.07	97.49
2	2	2015-12-13	0.93	118220.22	794.70	109149.67	130.50	8145.35	8042.21	103.14
3	3	2015-12-06	1.08	78992.15	1132.00	71976.41	72.58	5811.16	5677.40	133.76
4	4	2015-11-29	1.28	51039.60	941.48	43838.39	75.78	6183.95	5986.26	197.69

Read CSV and assign index You can assign columns as index using "index_col" attribute. Since I want to index Date there is another helpful function called "parse_date" which will parse the date in the rows such that we can perform more complex subsetting(eg monthly, weekly etc).

In [6]:
```
# read CSV from using pandas and assigning Date as index of the dataframe
avocado = pd.read_csv(r'D:\14th nov  avocado resume project\14th\RESUME PROJECT --
```

In [7]:
```
avocado.head()
```

Out[7]:

Date	Unnamed: 0	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	Large Bags
2015-12-27	0	1.33	64236.62	1036.74	54454.85	48.16	8696.87	8603.62	93.25
2015-12-20	1	1.35	54876.98	674.28	44638.81	58.33	9505.56	9408.07	97.49
2015-12-13	2	0.93	118220.22	794.70	109149.67	130.50	8145.35	8042.21	103.14
2015-12-06	3	1.08	78992.15	1132.00	71976.41	72.58	5811.16	5677.40	133.76

Remove index from dataframe .reset_index(drop)

To reset the index use this function

In [8]:
```
avocado = avocado.reset_index(drop = True)
```

In [9]:
```
avocado.head()
```

Out[9]:

	Unnamed: 0	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	Large Bags	XLarg Bag
0	0	1.33	64236.62	1036.74	54454.85	48.16	8696.87	8603.62	93.25	0
1	1	1.35	54876.98	674.28	44638.81	58.33	9505.56	9408.07	97.49	0
2	2	0.93	118220.22	794.70	109149.67	130.50	8145.35	8042.21	103.14	0
3	3	1.08	78992.15	1132.00	71976.41	72.58	5811.16	5677.40	133.76	0
4	4	1.28	51039.60	941.48	43838.39	75.78	6183.95	5986.26	197.69	0

To write a CSV file function dataframe.to_csv(FILE_NAME)

In [10]:
```
avocado.to_csv("test_write.csv")
```

Some useful pandas function

.head() or .head(x) is used to get the first x rows of the DataFrame (x = 5 by default)

In [11]:
```
avocado = pd.read_csv(r'D:\14th nov  avocado resume project\14th\RESUME PROJECT --
```

In [12]:
```
avocado.head()
```

Out[12]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	Large Bags
0	0	2015-12-27	1.33	64236.62	1036.74	54454.85	48.16	8696.87	8603.62	93.25
1	1	2015-12-20	1.35	54876.98	674.28	44638.81	58.33	9505.56	9408.07	97.49
2	2	2015-12-13	0.93	118220.22	794.70	109149.67	130.50	8145.35	8042.21	103.14
3	3	2015-12-06	1.08	78992.15	1132.00	71976.41	72.58	5811.16	5677.40	133.76
4	4	2015-11-29	1.28	51039.60	941.48	43838.39	75.78	6183.95	5986.26	197.69

.tail() or .tail(x) is used to get the last x rows of the DataFrame (x = 5 by default)

In [13]:
```
avocado.tail(10)
```

Out[13]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	La B

dtypes: float64(9), int64(2), object(3)
memory usage: 1.9+ MB
```

.shape is used to get the dimensions of the DataFrame

In [15]:
```
print(avocado.shape)
```

```
(18249, 14)
```

- **.describe()** is used to view some basic statistical details like percentile, mean, std etc. of a DataFrame

In [16]:
```
avocado.describe()
```

Out[16]:

	Unnamed: 0	AveragePrice	Total Volume	4046	4225	4770	To

- **.value** this attribute return a Numpy representation of the given DataFrame

In [17]:
```
avocado.values
```

Out[17]:
```
array([[0, '2015-12-27', 1.33, ..., 'conventional', 2015, 'Albany'],
       [1, '2015-12-20', 1.35, ..., 'conventional', 2015, 'Albany'],
       [2, '2015-12-13', 0.93, ..., 'conventional', 2015, 'Albany'],
       ...,
       [9, '2018-01-21', 1.87, ..., 'organic', 2018, 'WestTexNewMexico'],
       [10, '2018-01-14', 1.93, ..., 'organic', 2018, 'WestTexNewMexico'],
       [11, '2018-01-07', 1.62, ..., 'organic', 2018, 'WestTexNewMexico']],
      dtype=object)
```

.columns this attribute return a Numpy representation of columns in the DataFrame

In [18]:
```
print(avocado.columns)
```

```
Index(['Unnamed: 0', 'Date', 'AveragePrice', 'Total Volume', '4046', '4225',
       '4770', 'Total Bags', 'Small Bags', 'Large Bags', 'XLarge Bags', 'type',
       'year', 'region'],
      dtype='object')
```

Appending & Concatenating Series append(): Series & DataFrame method Invocation: s1.append(s2) Stacks rows of s2 below s1 concat(): pandas module function Invocation: pd.concat([s1, s2, s3]) Can stack row-wise or column-wise

In [19]:
```
even = pd.Series([2,4,6,8,10])
odd = pd.Series([1,3,5,7,9])

res = even.append(odd)
```

```
C:\Users\RUPA\AppData\Local\Temp\ipykernel_13628\3129502900.py:4: FutureWarning: T
he series.append method is deprecated and will be removed from pandas in a future
version. Use pandas.concat instead.
  res = even.append(odd)
```

In [20]:
```
res
```

Out[20]:
```
0     2
1     4
2     6
3     8
4    10
0     1
1     3
2     5
3     7
4     9
dtype: int64
```

Observe index got messed up

you can use .reset_index(drop = True)to fix it Note: if drop = False then previous index will be added as column

In [21]:
```
res.reset_index(drop=True)
```

Out[21]:
```
0     2
1     4
2     6
3     8
4    10
5     1
6     3
7     5
8     7
9     9
dtype: int64
```

Sorting

syntax:

DataFrame.sort_values(by, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last') by: Single/List of column names to sort Data Frame by. axis: 0 or 'index' for rows and 1 or 'columns' for Column. ascending: Boolean value which sorts Data frame in ascending order if True. inplace: Boolean value. Makes the changes in passed data frame itself if True. kind: String which can have three inputs('quicksort', 'mergesort' or 'heapsort') of algorithm used to sort data frame. na_position: Takes two string input 'last' or 'first' to set position of Null values. Default is 'last'.

In [22]:
```
# sort values based on "AveragePrice" (ascending) and "year" (descending)
avocado.sort_values(["AveragePrice", "year"], ascending=[True, False])
```

Out[22]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags
15261	43	2017-03-05	0.44	64057.04	223.84	4748.88	0.00	59084.32

18249 rows × 14 columns

sorting by index

use df.sort_index(ascending = True/False)

subsetting

subsetting is used to get a slice of the original dataframe

In [23]:
```
# subsetting columns
avocado["AveragePrice"]
```

Out[23]:
```
0        1.33
1        1.35
2        0.93
3        1.08
4        1.28
         ...
18244    1.63
18245    1.71
18246    1.87
18247    1.93
18248    1.62
Name: AveragePrice, Length: 18249, dtype: float64
```

subsetting multiple columns

In [24]:
```
# subsetting multiple columns
avocado[["AveragePrice", "Date"]]
```

Out[24]:

	AveragePrice	Date
0	1.33	2015-12-27
1	1.35	2015-12-20
2	0.93	2015-12-13
3	1.08	2015-12-06
4	1.28	2015-11-29
...	...	...
18244	1.63	2018-02-04
18245	1.71	2018-01-28
18246	1.87	2018-01-21
18247	1.93	2018-01-14
18248	1.62	2018-01-07

18249 rows × 2 columns

then using it for subsetting the original dataframe

In [25]:
```
# This will print only the row with price < 1
avocado[avocado["AveragePrice"]<1]
```

Out[25]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Sm Ba

540 rows × 14 columns

subsetting based on multiple conditions

You can use the logical operators to define a complex condition

"&" and

"|" or

"~" not

SEPERATE EACH CONDITION WITH PARENTHESES TO AVOID ERRORS

In [28]:
```
# it will print all the rows with "Date" before 2015-02-04 and "type" == "organic"
avocado[(avocado["Date"]<"2015-02-04") & (avocado["type"]=="organic")]
```

Out[28]:

270 rows × 14 columns

Subsetting using .isin() isin() method helps in selecting rows with having a particular(or Multiple) value in a particular column Syntax: DataFrame.isin(values) Parameters: values: iterable, Series, List, Tuple, DataFrame or dictionary to check in the caller Series/Data Frame. Return Type: DataFrame of Boolean of Dimension.

In [29]:
```
# subset the avocado in the region Boston or SanDiego
regionFilter = avocado["region"].isin(["Boston", "SanDiego"])
avocado[regionFilter]
```

Out[29]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Sma Bag

676 rows × 14 columns

Multiple parameter Filtering

Use logical operators to combine different filters

In [30]:
```
# subset the avocado in the region Boston or SanDiego in the year 2016 or 2017
regionFilter = avocado["region"].isin(["Boston", "SanDiego"])
yearFilter = avocado["year"].isin(["2016", "2017"])
avocado[regionFilter & yearFilter]
```

Out[30]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	Large Bags	XLarge Bags	type

In [31]:
```
avocado.head()
```

Out[31]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	Large Bags
0	0	2015-12-27	1.33	64236.62	1036.74	54454.85	48.16	8696.87	8603.62	93.25
1	1	2015-12-20	1.35	54876.98	674.28	44638.81	58.33	9505.56	9408.07	97.49

4	4	2015-11-29	1.28	51039.60	941.48	43838.39	75.78	6183.95	5986.26	197.69

Detecting missing values .isna()

.isna() is a method used to find is there exist any NaN values in the DataFrame

It will give a True bool value if a cell has a NaN value

In [32]:
```
avocado.isna()
```

Out[32]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags	Large Bags	XLarge Bags
0	False	False	False	False	False	False	False	False	False	False	False
1	False	False	False	False	False	False	False	False	False	False	False
2	False	False	False	False	False	False	False	False	False	False	False
3	False	False	False	False	False	False	False	False	False	False	False
4	False	False	False	False	False	False	False	False	False	False	False
...	...	...	...	...	...	...	...	...	...	...	...
18244	False	False	False	False	False	False	False	False	False	False	False
18245	False	False	False	False	False	False	False	False	False	False	False
18246	False	False	False	False	False	False	False	False	False	False	False
18247	False	False	False	False	False	False	False	False	False	False	False
18248	False	False	False	False	False	False	False	False	False	False	False

18249 rows × 14 columns

we can use .any()function to get a consise info

In [33]:
```
avocado.isna().any()
```

Out[33]:
```
Unnamed: 0      False
Date            False
AveragePrice    False
Total Volume    False
4046            False
4225            False
4770            False
Total Bags      False
Small Bags      False
Large Bags      False
XLarge Bags     False
type            False
year            False
region          False
dtype: bool
```

counting missing values

In [34]:
```
avocado.isna().sum()
```

Out[34]:
```
Unnamed: 0      0
Date            0
AveragePrice    0
Total Volume    0
4046            0
4225            0
4770            0
Total Bags      0
Small Bags      0
Large Bags      0
XLarge Bags     0
type            0
year            0
region          0
dtype: int64
```

Removing missing values

1.Drop NaN dropna() 2.Fill NaN with valuex fillna(x)

In [35]:
```
# Luckily we don't have any NaN but if we have we can use any of the two methods

avocado.dropna()

# ****  OR  ****

meanVal = avocado["AveragePrice"].mean()
avocado.fillna(meanVal)
```

Out[35]:

18249 rows × 14 columns

Adding a new column

It can easily be done using the[]brackets

Lets add a new column to our dataframe called AveragePricePer100

In [36]:
```
avocado["AveragePricePer100"] = avocado["AveragePrice"] * 100
avocado
```

Out[36]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags
0	0	2015-12-27	1.33	64236.62	1036.74	54454.85	48.16	8696.87	8603.62
1	1	2015-12-20	1.35	54876.98	674.28	44638.81	58.33	9505.56	9408.07
2	2	2015-12-13	0.93	118220.22	794.70	109149.67	130.50	8145.35	8042.21
3	3	2015-12-06	1.08	78992.15	1132.00	71976.41	72.58	5811.16	5677.40

18249 rows × 15 columns

Deleting columns in DataFrame .drop(lst,axis = 1)

dataFrame.drop(['COLUMN_NAME'], axis = 1)

the first parameter is a list of columns to be deleted

axis = 1 means delete column

axis = 0 means delete row

In [37]:
```
avocado.drop(["AveragePricePer100"],axis = 1)
```

Out[37]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags

18249 rows × 14 columns

Summary statistics

some of the functions availabe in pandas are:

.median().mode().min().max().var().std().sum().quantile()

In [38]:
```
# mean of the AveragePrice of avocado
avocado["AveragePrice"].mean()
```

Out[38]:
```
1.405978409775878
```

Summarizing dates

To find the min or max date in a dataframe

In [39]:
```
avocado["Date"].max()
```

Out[39]:
```
'2018-03-25'
```

.agg() method

Pandas Series.agg() is used to pass a function or list of function to be applied on a series or even each element of series separately.

Syntax: Series.agg(func, axis=0)

Parameters: func: Function, list of function or string of function name to be called on Series. axis:0 or 'index' for row wise operation and 1 or 'columns' for column wise operation.

Return Type: The return type depends on return type of function passed as parameter.

In [40]:
```
def pct30(column):
    #return the 0.3 quartile
    return column.quantile(0.3)
def pct50(column):
    #return the 0.5 quartile
    return column.quantile(0.5)

avocado[["AveragePrice","Total Bags"]].agg([pct30,pct50])
```

Out[40]:

	AveragePrice	Total Bags
pct30	1.15	7316.634
pct50	1.37	39743.830

Dropping duplicate names.drop_duplicates(lst)

Delete all the duplicate names from the dataframe

In [41]:
```
temp = avocado.drop_duplicates(subset=["year"])
temp
```

Out[41]:

	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	Total Bags	Small Bags
0	0	2015-12-27	1.33	64236.62	1036.74	54454.85	48.16	8696.87	8603.62
2808	0	2016-12-25	1.52	73341.73	3202.39	58280.33	426.92	11432.09	11017.32
5616	0	2017-12-31	1.47	113514.42	2622.70	101135.53	20.25	9735.94	5556.98
8478	0	2018-03-25	1.57	149396.50	16361.69	109045.03	65.45	23924.33	19273.80

Count categorical data .value_counts()

Pandas Series.value_counts() function return a Series containing counts of unique values.

Syntax: Series.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Parameter : normalize : If True then the object returned will contain the relative frequencies of the unique values. sort : Sort by values. ascending : Sort in ascending order. bins : Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data. dropna : Don't include counts of NaN.

Returns : counts : Series

In [42]:
```
# count number of avocado in each year in descending order
avocado["year"].value_counts(sort=True, ascending = False)
```

Out[42]:
```
2017    5722
2016    5616
2015    5615
2018    1296
Name: year, dtype: int64
```

Grouped summaries .groupby(col)

This function will group similar categories into one and then we can perform some summary statistics

Syntax: DataFrame.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=False, **kwargs)

Parameters : by : mapping, function, str, or iterable axis : int, default 0 level : If the axis is a MultiIndex (hierarchical), group by a particular level or levels as_index : For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. as_index=False is effectively "SQL-style" grouped output sort : Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. groupby preserves the order of rows within each group. group_keys : When calling apply, add group keys to index to identify pieces squeeze : Reduce the dimensionality of the return type if possible, otherwise return a consistent type

Returns : GroupBy object

In [43]:
```
# group by multiple columns and perform multiple summary statistic operations
avocado.groupby(["year","type"])["AveragePrice"].agg([min,max,np.mean,np.median])
```

Out[43]:

year	type	min	max	mean	median
2015	**conventional**	0.49	1.59	1.077963	1.08
	organic	0.81	2.79	1.673324	1.67
2016	**conventional**	0.51	2.20	1.105595	1.08
	organic	0.58	3.25	1.571684	1.53
2017	**conventional**	0.46	2.22	1.294888	1.30
	organic	0.44	3.17	1.735521	1.72
2018	**conventional**	0.56	1.74	1.127886	1.14
	organic	1.01	2.30	1.567176	1.55

Pivot table

A pivot table is a table of statistics that summarizes the data of a more extensive table.

IMPORRANT paremeents to remember are
"index": it is the value that appeares on the left most side of the table (it can be a list)
"columns": these are the column you want to add to the pivot table
"aggfunc": it will call the function (it can be a list)
"values": it is the attribute which will be summarized in the table (values inside the table)

> Syntax
> pandas.pivot_table(data, values=None, index=None, columns=None,
> aggfunc='mean', fill_value=None, margins=False, dropna=True,
> margins_name='All')
>
> Parameters:
> data : DataFrame
> values : column to aggregate, optional
> index: column, Grouper, array, or list of the previousv columns: column,
> Grouper, array, or list of the previous
>
> aggfunc: function, list of functions, dict, default numpy.mean
> ....If list of functions passed, the resulting pivot table will have hierarchical
> columns whose top level are the function names.
> ....If dict is passed, the key is column to aggregate and value is function or list
> of functions
> fill_value[scalar, default None] : Value to replace missing values with
> margins[boolean, default False] : Add all row / columns (e.g. for subtotal /
> grand totals)
> dropna[boolean, default True] : Do not include columns whose entries are all
> NaN
> margins_name[string, default 'All'] : Name of the row / column that will
> contain the totals when margins is True.

> Returns: DataFrame

In [44]:
```
# this is the same table we build in the previous cell but using pivot table
avocado.pivot_table(index=["year","type"], aggfunc=[min,max,np.mean,np.median], val
```

Out[44]:

		min	max	mean	median
		AveragePrice	AveragePrice	AveragePrice	AveragePrice
year	type				
2015	conventional	0.49	1.59	1.077963	1.08
	organic	0.81	2.79	1.673324	1.67
2016	conventional	0.51	2.20	1.105595	1.08
	organic	0.58	3.25	1.571684	1.53
2017	conventional	0.46	2.22	1.294888	1.30
	organic	0.44	3.17	1.735521	1.72

	organic	1.01	2.30	1.567176	1.55

Explicit indexes

Indexes make subsetting simpler using .loc and .iloc

setting column as the index

In [45]:
```
regionIndex = avocado.set_index(["region"])
regionIndex
```

Out[45]:

region	Unnamed: 0	Date	AveragePrice	Total Volume	4046	4225	4770	To Ba

Arithmetic with Series & DataFrames You can use arithmetic operators directly on series but sometimes you need more control while performing these operations, here is where these explicit arithmetic functions come into the picture Add/Subtract function (just replece add with sub) Syntax: Series.add(other, level=None, fill_value=None, axis=0) Parameters: other: other series or list type to be added into caller series fill_value: Value to be replaced by NaN in series/list before adding level: integer value of level in case of multi index Return type: Caller series with added values Multiplication function Syntax: Series.mul(other, level=None, fill_value=None, axis=0) Parameters: other: other series or list type to be added into caller series fill_value: Value to be replaced by NaN in series/list before adding level: integer value of level in case of multi index Return type: Caller series with added values Division function Syntax: Series.div(other, level=None, fill_value=None, axis=0) Parameters: other: other series or list type to be divided by the caller series fill_value: Value to be replaced by NaN in series/list before division level: integer value of level in case of multi index Return type: Caller series with divided values

In [51]:
```
# subtract AveragePrice with AveragePrice :P
# Dah its 0
avocado["AveragePrice"].sub(avocado["AveragePrice"])
```

Out[51]:
```

```

Merge DataFrames Syntax: DataFrame.merge(self, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None) → 'DataFrame'[source]¶ Merge DataFrame or named Series objects with a database-style join. The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. Parameters right:

DataFrame or named Series Object to merge with. how{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘inner’ on: label or list Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames. left_on: label or list, or array-like Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns. right_on: label or list, or array-like Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns. left_index: bool, default False Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels. right_index: bool, default False Use the index from the right DataFrame as the join key. Same caveats as left_index. sort: bool, default False Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword). suffixes: tuple of (str, str), default (‘_x’, ‘_y’) Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False). Join DataFrame.merge(self, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None) → 'DataFrame'[source]¶ Merge DataFrame or named Series objects with a database-style join. The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. Parameters rightDataFrame or named Series Object to merge with. how{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘inner’ on: label or list Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames. left_on: label or list, or array-like Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns. right_on: label or list, or array-like Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns. left_index: bool, default False Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels. right_index: bool, default False Use the index from the right DataFrame as the join key. Same caveats as left_index. sort: bool, default False Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword). suffixes: tuple of (str, str), default (‘_x’, ‘_y’) Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).
